1. **Industrial Grade (High Tenacity) Fibers**

Fibers are the foundation for all twine, cables, cordage, rope, and netting products. In the past ten years, there have been many new developments in fibers. It is important; therefore, that engineers and users understand and appreciate the "building blocks" of any strength member product.

Historically, cordage, ropes and twines were made from natural (vegetable) fibers. While these are still important for some applications, virtually all modern cordage products are based on synthetic fibers.

For the purpose of this document industrial grade fibers used in quality cordage and rope are synthetic fibers with a tenacity up to 15 grams per denier (gpd). High tenacity fibers used in quality cordage and rope are synthetic fibers with a tenacity above 15 grams per denier (gpd).

Many synthetic fibers can have a pigment added during the manufacturing process resulting in permanent color. A variety of colors are available.

1.1 **Polyamide (Nylon)**

The first man-made fiber used in cordage was nylon. It is a manufactured fiber composed of linear macromolecules having in the chain recurring amide linkages, at least 85% of which are joined to aliphatic or cycloaliphatic units. Two types of nylon are commonly used in rope making. Nylon 6 is made from amino caprolactam. Nylon 6,6 is made from hexamethylene diamine and adipic acid. The principal property difference is melt point.

The proper chemical name for nylon is polyamide. Chemical abbreviation PA; Chemical formula:

\[ \text{-NH-} (\text{CH}_2)_5 \text{-CO-} \_n \text{ (nylon 6), and} \]
\[ \text{-NH-} (\text{CH}_2)_6 \text{-NH-} \text{CO}(\text{CH}_2)_4\text{-CO-} \_n \text{ (nylon 6,6).} \]

Fiber tenacity ranges are from 7.5 to over 10.5 gpd.

1.2 **Polyester**

A manufactured fiber produced from the linear polymer 'polyethylene terephthalate'. Chem. abbr. PET (PES is also sometimes used);

Chem. form.: \([-\text{OC-} \text{C}_6\text{H}_4 \text{-COO-CH}_2\text{-CH}_2\text{-0}]\).

More generally, polyester includes polymers composed of linear macromolecules having in the chain at least 85% by mass of an ester of a diol and terephthalic acid. Such linear polyesters are fiber forming.

Tenacity ratings of industrial polyester fibers range from 7.0 gpd to over 10.0 gpd.
1.3 Polyolefins
A class of polymers in which the fiber-forming substance is any long-chain synthetic polymer composed of at least 85% by weight of ethene (ethylene), propane (propylene), or other olefin units. This class includes Polypropylene and Polyethylene.

1.3.1 Polypropylene
A manufactured fiber formed by melt spinning and drawing polymers or copolymers of propylene, an aliphatic saturated hydrocarbon linear macromolecule where one carbon atom in two carries a methyl side chain in an isostatic disposition and without further substitution.
Chem. abbr. PP; chem. form. -(CH2-CH)-
\[
\text{CH}_3
\]

1.3.2 Polyethylene
A manufactured fiber formed of polymers of ethylene, synthetic linear macromolecules of unsubstituted aliphatic saturated hydrocarbon.
Chem. abbr. PE; chem. form. -(CH2-CH2)-

1.3.3 Copolymer Fibers
Copolymer is the industry term for the melt combination of olefin polymer(s) (polypropylene/polyethylene) together or with other polymer(s) such as polyester. In most cases, copolymer combinations are based on proprietary formulas.

1.4 Fluoropolymers
A class of fluorocarbon based polymers with very strong carbon-fluorine bonds which are inherently chemically stable.

1.4.1 Expanded Polytetrafluoroethylene (ePTFE)
A manufactured fiber formed of long polymer chains of PTFE stretched into nodes and fibrils.
Chem. form.: -(CnF2n)-

2. Combination, Duplex, or Blended Fibers
Cordage and rope can be made with the properties of more than one fiber by combining them in a single construction. In stranded and single-braided ropes, this is usually done by the combining of yarns or filaments of different fibers in the making of strands. In double-braided ropes this can also be done by using one type of fiber in the core and another in the cover, by utilizing differences in the fiber characteristics through the braid design.
3. **Natural Fibers**

   **NOTE:** Ropes made from natural fibers can lose significant strength under normal storage conditions. For this reason, natural fiber ropes should NOT be used in applications where life and limb is at risk.

   Natural fibers are classified as hard fibers and soft fibers. Generally speaking, hard fibers form the structural system of the leaf or plant, and soft fibers are found in the bast layer of the plant stem.

   3.1 **Abaca (manila):** Abaca is obtained from the tropical plant Musa Textilis, a member of the banana plant family. It is commonly known as Manila hemp, which is a misnomer since the hemp plant belongs to the soft fiber group. Abaca is the strongest of the natural fibers. The majority of manila is grown in the Philippines.

   3.2 **Sisal and henequen:** Sisal (Agave sisalana) and henequen (A. fourcroydes) are hard fibers. Henequen is sometimes called Mexican or Cuban sisal. Various sisals are identified by country of origin: Brazil, Haiti, Kenya, Tanzania, and Indonesia being the major producers.

   3.3 **Others:** Jute is a soft fiber and comes from two closely related plants: Corchorous capsularia and C. olitorius. Hemp is a soft fiber and comes from the Cannabis sativa plant. Cotton is a natural fiber widely used in the textile industry, including some cordage and smaller diameter ropes. Cotton is often blended with synthetic staple fibers for additional strength and improved abrasion resistance.

4. **High-Performance High-Modulus Fibers**

   These fibers have a tenacity greater than 15.0 grams/denier (gpd). The first of these was paraaramid (1970’s) followed by High Modulus PolyEthylene (HMPE, 1980’s) and liquid crystal polyester (LCP, 1990’s).

   4.1 **Para-aramid fibers.** A manufactured high-modulus fiber in which the fiber-forming substance is a long chain synthetic aromatic polyamide in which at least 85% of the amide linkages are attached directly to two aromatic rings.

   4.2 **High Modulus PolyEthylene (HMPE).** A polyolefin fiber produced by gel spinning or solid-state extrusion of an Ultra High Molecular Weight PolyEthylene (UHMWPE) feedstock to produce extremely high tenacity. Also called Extended-Chain PolyEthylene (ECPE) or High-Performance PolyEthylene (HPPE).

   4.3 **Liquid Crystal Polyester, (LCP).** A thermotropic liquid crystal aromatic polyester fiber produced by melt spinning. It is a high-performance multifilament yarn with high tenacity and modulus. Also known as polyester-arylate.

   4.4 **PBO.** PBO is a poly-para-phenylene bisoxazole fiber. PBO is polymerized from diaminoresocinol dichloride and terephthalic acid in polyphosphoric acid.
Long term properties are dependent on end use and environment. Always consult the rope manufacturer before choosing a rope for extended service.

Notes:
Note 1: Resistance to abrasion is relative to other industrial fibers in this chart
Note 2: LDPE is Low Density Polyethylene
Note 3: Natural fibers are subject to degradation by fungal/bacterial attack during storage. Ropes made from natural fibers should not be used in applications where life and limb are at risk.

This information is provided by the fiber manufacturers and is not intended as a Cordage Institute endorsement.

Fiber selection should involve discussions with both fiber and cordage manufacturers. Special overlay finishes are available to enhance the strength and abrasion resistance. See page 7 for fiber producers contact information.

Para-aramid Copolymer has low creep rates. It also has fair UV resistance and should be protected when exposed to sunlight.  
Abrasion resistance is good.  
Resistant to acids, bases and organic solvents |
| **HMPE (1) (gel spun)** | **Dyneema®**, Spectra®, Doyentron®, IZANAS® | White | 0.97 | 25-44 | 2.1-3.8 | 68-145 | 2.5-3.9 | 70 °C | MP 143-155 °C | 0.0 | Gel-spun HMPEs have excellent abrasion resistance and good UV resistance. At higher loads and/or temperatures, creep resistance can be a concern.  
Resistant to most concentrated industrial acids, bases, oxidizers, and organic solvents at room temperature. Resistant to many acids/bases/oxidizers/solvents at elevated temperatures. |
| **HMPE (solid state)** | **Endumax®** | White | 0.97 | 28 | 2.4 | 175 | 1.9 | 80 °C | MP 143-155 °C | 0.0 | HMPE (solid state) has good abrasion resistance and good UV resistance. At higher loads and/or temperatures, creep resistance can be a concern.  
Resistant to most concentrated industrial acids, bases, oxidizers, and organic solvents at room temperature. Resistant to many acids/bases/oxidizers/solvents at elevated temperatures. |
| **PBO (1)** | **ZYLON®** | Gold | 1.54-1.56 | 42 | 5.7 | 175-275 | 2.5-3.5 | 400 °C | Does not melt Decomposes @ 600°C | 0.6-2.0 | PBO has very low creep rates and low abrasion resistance. It has poor UV resistance and should be protected when exposed to sunlight.  
Resistant to bases and organic solvents at room temperature. Degradation induced by strong acids. |

**Physical Property Definitions:**
- **Breaking Tenacity:** break load in grams force per denier weight.
- **Breaking Strength:** break load divided by fiber cross sectional area.
- **Modulus:** resistance to stretch, or slope of load-elongation curve.
- **Elongation at Break:** change in yarn length at break, expressed as percent of initial gage length.
- **Moisture regain tested at standard conditions of 72 deg F at 65% relative humidity.

**Long-Term / Environmental Property Definitions:**
- **Long term properties are dependent on end use and environment.** Always consult the rope manufacturer before choosing a rope for extended service. Repapersmakers should be consulted if ropes are to be used in extreme heat or cold.  
- **Creep – Gradual change in length under the effects of an applied static tensile load. Influenced by testing temperature and applied load.**  
- **Abrasion – Reduction in strength caused by interaction with surrounding fibers or surface.** Overlap finishes and lubricants can enhance abrasion resistance under both wet and dry conditions.  
- **Sunlight/UV - Synthetic fibers are susceptible to degradation on direct exposure to sunlight. Degradation of fibers within a rope can vary depending on rope construction, coatings and other factors.**  
- **Chemical Exposure – Fibers may be chemically degraded by exposure to specific agents.** Data on chemical resistance should be obtained from the fiber companies, as listed on page 7, and the rope manufacturers.

**Notes:**
- Note 1: HMPE is High Modulus Polyethylene.  
- Note 2: PBO is Poly-Paraphenylene-2,6 Benziodizoxazole.  
- This information is provided by the fiber manufacturers and is not intended as a Cordage Institute endorsement.  
- Fiber selection should involve discussions with both fiber and cordage manufacturers.  
- Special overlap finishes are available to enhance the strength and abrasion resistance. See page 7 for fiber producers contact information.
Cordage Institute Member Fiber Producers

Beijing Tongyizhong Specialty Fiber Technology & Development Co., Ltd
Nina Zhang
No.16 Zhonghe Street, Economic & Technological Development Area
Beijing, China
